

## M01 RAW SYSTEM WIRING

06-18-07

This document, originally written by Ross Doyle back in the 1980s, is supplied for reference only. Much of the information contained in its pages is obsolete, fragmented or just flat wrong. For electronic service information refer to the most recent schematic drawings dated June 2007 and drawn by Daniel Schoo.

The updated drawings were the result of a careful investigation of the M01 RAW water control system as found. As such some things do not seem to make sense. You would be correct in that assumption. Many of the circuits were never implemented, removed or changed with little attention to professional practice. Some parts have no purpose and other parts are missing.

The drawings were not intended to improve the system but to document it as it is and to facilitate repairing it when it failed.

Daniel Schoo

# M01 RAW SYSTEM OPERATION

*Rev. 11/14/89*

This is a totally new type of Closed Loop Water Cooling system designed for the ease of replacement, repair, uniformity, portability, computer readouts, and variable flow rates. This system has the rated capacity of 150 KW. and flow rates from 5 g.p.m. to 60 g.p.m., with a constant pressure of 115 p.s.i. and is known as the RAW System (radioactive water).

Incorporated in this system is the following;

Where the loads required cooling water at a lower temperature or have the max. load of 150 KW. we have installed an ICW heat exchanger that precools the LCW to a lower temperature, this portion of the system is not used. This eliminates the need for costly and complicated chillers that have been used in the past. This system does require the LCW cooling to satisfy the Radiation Safety Group, but not the ICW. The surge tank in this system is open to the atmosphere to release any hydrogen build-up that may occur and eliminates the need for recombiners and extra alarms. The RAW system has two temperature readouts and one flow readout, these are analog readouts and may be processed by the main computer system. There are (13) status points that are available from these systems along with the (3) analog points. These status points will indicate if a pump is operating, if the flow is proper, if the temperature is ok, if the surge tank is at the proper level, ect.. This system had many other interlocks and status points but they have been jumpered because the chiller was never required.

The reason for having a semi-portable system with extra interlocks and status readouts, is to try and eliminate the "Johnson Control Syndrome" that all departments were chained to in the past. This system was the prototype for all of the new RAW systems and is not identical with all of the other RAW systems.

The main control box for this system is located in MS-1 for a visual readout of the system that it is operating. The front face of the control box is diagramed to give the operator a flow diagram of the system, and indicates the proper flows and temperatures. The lights on the front of the control box give the operator an instant look at the system, if the lights are green then the system is ok, if red other than the spare pump or the lights that indicate that they are jumpered, then there is a problem.

## System Operation

Raw water from the pump is pushed to the load of the system. The RAW water removes the heat build-up from the load and returns through the LCW to RAW heat exchanger to remove the heat. After the LCW to RAW heat exchanger the RAW water is returned to the suction side of the RAW pump. The supply and return temperatures, and flow is monitored in this loop. LCW from the main LCW system enters the ICW to LCW heat exchanger through the LCW flow regulator ( adj. from 10-60 g.p.m.) this precools the LCW if required. After the ICW to LCW heat exchanger the LCW enters the LCW to RAW heat exchanger removing the heat from the RAW water and then returns to the main LCW system. All RAW systems require LCW cooling and are interlocked with the LCW flow switch. If precooling is required, then the system is interlocked with the ICW flow or pressure switch.

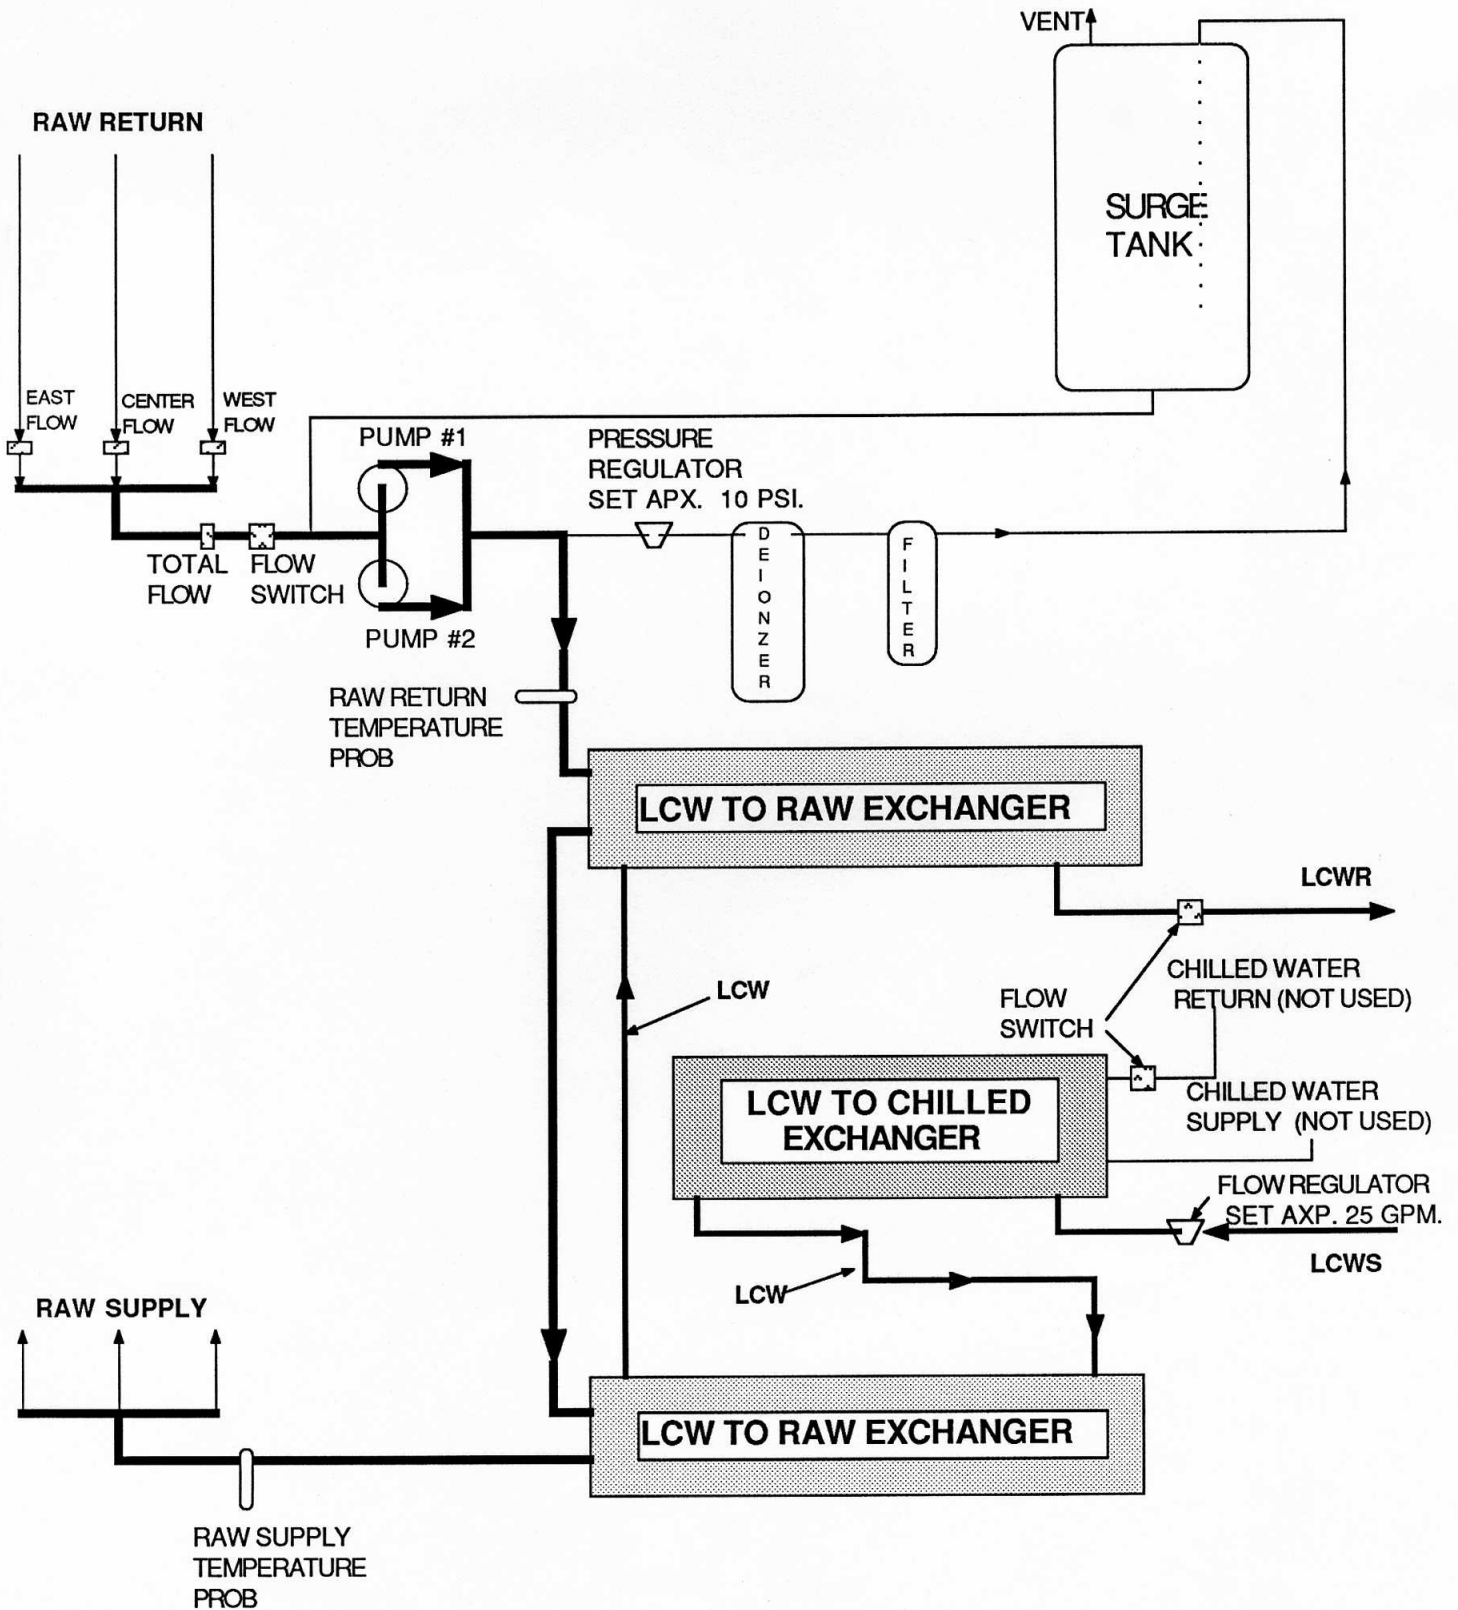

Apx. 5 g.p.m. of the RAW water is pushed through the deionizing loop at a pressure of 10 p.s.i. then through the string filter and back to the surge tank. When the water is made-up it passes through the deionizing loop and filter before entering the surge tank. To change the deionizing bottle or filter the system must be off. The valves on the deionizing loop must be closed. To make-up water manually close the 3/4" valve before the deionizing loop, pressure regulator. Open the valve marked make-up. Fill the surge tank 3" from the top of the sight glass. Close the make-up valve. Reopen the 3/4" valve before the pressure regulator.

To start a system, select pump #1 or pump #2. The valves for the selected pump must be open and closed for the other. Check that the surge tank normal. Check that the LCW flow is OK. Push the start and the reset button, until the RAW total flow light changes from red to green, release the start and reset button. All lights should be green except for the spare pump and the readouts that are jumpered. The flow set point is indicated by tape on the flow indication meter.

The temperature is read by panel meters in degrees Celsius. The supply temperature will trip the system if the temperature exceeds the trip point. The return temperature will only send an alarm. The set point may be checked by rotating the knob or the front of the control box from actual to set. The temperature is now set at 49 deg c.= 120 f. This may change due to different loads.
